Time required: 60 minutes

DRY

Don't Repeat Yourself

Learning Outcomes

Students will be able to:

- Write different types of loops, such as for and while
- Select the correct type of loop based on a given problem
- Use loops to solve common problems, such as, finding sum, finding max, etc.
- Write nested loops

Read: Think Java 2

• Chapter 6 Loops and Strings

Do: Java Tutorials

- Java While Loop
- Java For Loop
- Java For-Each Loop
- Java Break and Continue

Tutorial 4.1 - For Loop Numbers and Squares

Create a Java program named: NumbersAndSquares.java

```
// Written by:
// Written on:
// Purpose: Use a for loop to print the squares
// and cubes of the numbers 1 to 10
public class NumbersAndSquares {
    Run | Debug
    public static void main(String[] args) {
       String DASHES = "----";
        int square = 0;
        int cube = 0;
        System.out.println(DASHES);
        System.out.println("Number\tSquare\tCube");
        System.out.println(DASHES);
        for (int i = 1; i < 11; i++) {
           // Calculate the square of the current number
            square = i * i;
            cube = i * i * i;
            System.out.println(i + "\t" + square + "\t" + cube);
        System.out.println(DASHES);
```

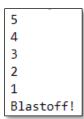

```
Square
                Cube
        1
1
                 1
2
        4
                 8
        9
                 27
        16
                 64
        25
                 125
6
        36
                 216
        49
                 343
8
        64
                 512
        81
                 729
10
        100
                 1000
```

Tutorial 4.2 - For Loop Blast Off!

Here is an example program that counts down from 5 and then prints a message. We imported the **sleep** method from the **TimeUnit** library, to count down 1 second at a time.

```
1 // Name: BlastoffForLoop.java
 2 // Written by:
3 // Written on:
4 // Purpose: Count backwards with sleep to emulate
5 // a blastoff countdown
7 // Import TimeUnit library for sleep method
8 import java.util.concurrent.TimeUnit;
9
10 public class BlastoffForLoop {
11
       public static void main(String[] args) {
12
           // A for loop from 5 - 1
13
           for (int i = 5; i > 0; i--) {
14
               System.out.println(i);
15
16
               // Code block to sleep for 1 second
17
               try {
18
                   TimeUnit.SECONDS.sleep(1);
19
               } catch (InterruptedException e) {
20
                   Thread.currentThread().interrupt();
21
22
23
           System.out.println("Blastoff!");
24
       }
25 }
```

Example program run:

Tutorial 4.3 - Running Total While Loop

The following program demonstrates how to keep a running total of numbers entered by the user.

Create a Java program named: RunningTotal.java

```
1 // Name: RunningTotal.java
2 // Written by:
3 // Written on:
4 // Purpose: Sum a series of numbers entered by the user with a while loop
6 // Import Scanner library for input
7 import java.util.Scanner;
8
9 public class RunningTotal {
10
      public static void main(String[] args) {
11
          // Declare Scanner object and initialize with
12
          // predefined standard input object, System.in
13
          Scanner keyboard = new Scanner(System.in);
14
15
          // Declare variables for input and running total
16
          double runningTotal = 0;
17
          double number;
18
19
          // Print the heading and prompt
20
          System.out.println("+-----");
          21
22
23
24
          while (true) {
25
              System.out.print("Enter a number (0 to quit): ");
26
              // Get double from the keyboard
             // Assign double to variable
27
28
              number = keyboard.nextDouble();
29
             // If the user types in the sentinel value 0
30
              // Break the loop
31
             if (number == 0) {
32
                 break;
33
34
             // Accumulate running total
35
              runningTotal += number;
36
          }
37
38
          // # Display the running total
39
          System.out.println("The total is: " + runningTotal);
40
41
          keyboard.close();
42
      }
43 }
```

Input Validation and Exception Handling

Exception handling ensures that the correct data type is input by the user. If the user enters a string when an integer is what the program wants, this will generate a program exception.

Input validation ensures that the input is in the right range. An age should be positive. A bank withdrawal would be negative.

For example, if you want users to enter their ages, your code shouldn't accept nonsensical answers such as negative numbers (which are outside the range of acceptable integers) or words (which are the wrong data type). Input validation can also prevent bugs or security vulnerabilities.

If you implement a withdraw_from_account() function that takes an argument for the amount to subtract from an account, you need to ensure the amount is a positive number. If the withdraw_from_account() function subtracts a negative number from the account, the "withdrawal" will end up adding money!

Typically, we perform input validation by repeatedly asking the user for input until they enter valid input, as in the following example:

Tutorial 4.4 - Input Validation Try Except While

```
1 // Name: InputValidation.java
2 // Written by:
3 // Written on:
4 // Purpose: Validate the correct user input
5 // with try except and if
7 // Import Scanner library for user input
8 import java.util.Scanner;
10 public class InputValidation {
11
       public static void main(String[] args) {
12
           // Declare Scanner object and initialize with
13
           // predefined standard input object, System.in
14
           Scanner keyboard = new Scanner(System.in);
15
16
           int age = 0;
17
           String input;
18
19
           while (true) {
20
               // Try to get valid integer input
21
               try {
22
                   System.out.print("Enter your age: ");
23
                   // Get String from the keyboard
24
                   input = keyboard.nextLine();
25
                   // Parse input into integer
26
                   // assign to variable
27
                   age = Integer.parseInt(input);
28
               } catch (Exception e) {
29
                   // Handle execption
30
                   // If input is not an integer
31
                   System.out.println("Please use a whole number.");
32
                   // Start the loop over
33
                   continue;
34
```

Sample run:

```
35
               // Is the integer a positive number
36
               if (age < 1) {
37
                   System.out.println("Please enter a positive number.");
38
                   // Start the loop over
39
                   continue;
40
               } else {
41
                   // Break out the loop with valid input
42
                   break;
43
44
           }
45
           // Input is valid
           System.out.println("Your age is : " + age);
46
47
           keyboard.close();
48
       }
49 }
```

```
Enter your age: bi
Please use a whole number.
Enter your age: -25
Please enter a positive number.
Enter your age: 66
Your age is : 66
```

When you run this code, you'll be prompted for your age until you enter a valid one. This ensures that by the time the execution leaves the while loop, the age variable will contain a valid value that won't crash the program.

Tutorial 4.5 - Nested for Loop

You can place a loop inside a loop.

Create a Java program named **NestedLoopsDemo.java**

```
1 // Name: NestedLoopDemo.java
2 // Written by:
3 // Written on:
4 // Purpose: Use a nested loop
6 public class NestedLoopsDemo {
7
8
     public static void main(String[] args) {
9
        System.out.println("====== Nested Loop Demo =======");
10
        // Exterior loop
11
        for (int i = 0; i < 3; i++) {
12
          System.out.println("-----");
13
          System.out.println("-----");
14
          // Interior loop
          for (int j = 0; j < 5; j++) {
15
16
             System.out.print(j + "\t");
17
18
          System.out.println("\n");
19
        }
20
     }
21 }
```

Debugging

As you start writing bigger programs, you might find yourself spending more time debugging. More code means more chances to make an error and more places for bugs to hide.

One way to cut your debugging time is "debugging by bisection." For example, if there are 100 lines in your program and you check them one at a time, it would take 100 steps.

Instead, try to break the problem in half. Look at the middle of the program, or near it, for an intermediate value you can check. Add a print statement (or something else that has a verifiable effect) and run the program.

If the mid-point check is incorrect, the problem must be in the first half of the program. If it is correct, the problem is in the second half.

Every time you perform a check like this, you halve the number of lines you must search. After six steps (which is much less than 100), you would be down to one or two lines of code, at least in theory.

In practice it is not always clear what the "middle of the program" is and not always possible to check it. It doesn't make sense to count lines and find the exact midpoint. Instead, think about places in the program where there might be errors and places where it is easy to put a check. Then choose a spot where you think the chances are about the same that the bug is before or after the check.

Assignment Submission

- 1. Attach the pseudocode.
- 2. Attach the program files.
- 3. Attach screenshots showing the successful operation of the program.
- 4. Submit in Blackboard.
